

703308 VO High-Performance Computing The 13 Dwarfs of HPC

Philipp Gschwandtner

Overview

- ▶ The 13 Dwarfs of HPC
 - ▶ abstract application categories

Motivation

- ▶ MPI API or concepts such as data vs. task parallelism are still pretty low-level characteristics of parallel programs
- ▶ we need to be able to recognize higher-level classes of HPC applications and discuss them
- ▶ this lecture presents the most prominent classes of HPC applications
 - ▶ many new applications you encounter will fit into these categories or are a combination of them

How and why are dwarfs defined?

- ▶ group applications by similarity in computation and data structures
 - ▶ first published by Asanovic et al in *The Landscape of Parallel Computing Research: A View from Berkeley*
 - ▶ <https://www2.eecs.berkeley.edu/Pubs/TechRpts/2006/EECS-2006-183.pdf>
- ▶ purely algorithmic, implementation-independent
 - ▶ enables cross-platform reasoning and cross-application knowledge/resource sharing (e.g. libraries)
- ▶ serve as small, abstract, high-level benchmarks for studying new
 - ▶ programming models
 - ▶ communication patterns
 - ▶ hardware architectures, topologies
 - ▶ ...
- ▶ used to kick off innovation in all of these aspects

7 original dwarfs of HPC

- ▶ What are we going to discuss?
 - ▶ 1. Dense Linear Algebra
 - ▶ 2. Sparse Linear Algebra
 - ▶ 3. Spectral Methods
 - ▶ 4. N-body Methods
 - ▶ 5. Structured Grids
 - ▶ 6. Unstructured Grids
 - ▶ 7. Monte Carlo Methods
- ▶ What have you already heard?
 - ▶ matrix mul (first MPI lecture)
 - ▶ N-body
 - ▶ heat stencil
 - ▶ Monte Carlo π

Dense linear algebra

- ▶ data is stored in densely-populated matrices (or vectors)
 - ▶ data is stored uncompressed (“as is”)
 - ▶ data access via strides, often unit stride
- ▶ e.g. matrix multiplication, LU decomposition, Gauss-Seidel, ...
- ▶ rarely done manually, there are a TON of libraries out there

$$\begin{array}{|c|c|c|c|} \hline & \textcolor{white}{\boxed{}} & \textcolor{white}{\boxed{}} & \textcolor{white}{\boxed{}} \\ \hline \textcolor{orange}{\boxed{1}} & \textcolor{orange}{\boxed{1}} & \textcolor{orange}{\boxed{1}} & \textcolor{orange}{\boxed{1}} \\ \hline & \textcolor{white}{\boxed{}} & \textcolor{white}{\boxed{}} & \textcolor{white}{\boxed{}} \\ \hline \end{array} \times \begin{array}{|c|c|c|c|} \hline & \textcolor{white}{\boxed{}} & \textcolor{white}{\boxed{}} & \textcolor{orange}{\boxed{1}} \\ \hline & \textcolor{white}{\boxed{}} & \textcolor{white}{\boxed{}} & \textcolor{white}{\boxed{}} \\ \hline & \textcolor{white}{\boxed{}} & \textcolor{white}{\boxed{}} & \textcolor{white}{\boxed{}} \\ \hline & \textcolor{white}{\boxed{}} & \textcolor{white}{\boxed{}} & \textcolor{white}{\boxed{}} \\ \hline \end{array} = \begin{array}{|c|c|c|c|} \hline & \textcolor{lightblue}{\boxed{0}} & \textcolor{lightblue}{\boxed{0}} & \textcolor{orange}{\boxed{1}} \\ \hline & \textcolor{lightblue}{\boxed{0}} & \textcolor{lightblue}{\boxed{0}} & \textcolor{lightblue}{\boxed{0}} \\ \hline & \textcolor{lightblue}{\boxed{0}} & \textcolor{lightblue}{\boxed{0}} & \textcolor{lightblue}{\boxed{0}} \\ \hline & \textcolor{lightblue}{\boxed{0}} & \textcolor{lightblue}{\boxed{0}} & \textcolor{lightblue}{\boxed{0}} \\ \hline \end{array}$$

Dense linear algebra: characteristics

- ▶ naïve implementations usually memory bound
 - ▶ remember: memory wall!
 - ▶ caches and prefetching helps
- ▶ simple but significant data structure
 - ▶ stride often enables/prevents vectorization (SIMD)
 - ▶ fastest-changing index affects cache efficiency (hence matrices are often transposed)
- ▶ still the default measure for performance in HPC
 - ▶ e.g. TOP500 uses HPL, a high performance LINPACK benchmark
 - ▶ but nowadays not the only one (e.g. HPCG)

```
for (int i = 0; i < N; ++i) {  
    for (int j = 0; j < N; ++j) {  
        double tmp = 0.0;  
        for (int k = 0; k < N; ++k) {  
            tmp += A[i][k] * B[k][j];  
        }  
        result[i][j] = tmp;  
    }  
}
```

```
vgatherqpd ymm0{k2}, [rax+ymm5*1]  
vmulpd ymm0, ymm0, YMMWORD PTR [rdx+rdi]  
...
```

Side note: TOP500 list: Rmax vs. Rpeak

- ▶ **Rmax:** achieved by software
 - ▶ high performance linpack (HPL) benchmark
 - ▶ linear algebra stress-testing
- ▶ **Rpeak:** achievable by hardware
 - ▶ product of: number of FP units per CPU, their FP instructions per cycle, clock frequency, and number of CPUs

Rank	System	Cores	Rmax (PFlop/s)	Rpeak (PFlop/s)	Power (kW)
1	Frontier - HPE Cray EX235a, AMD Optimized 3rd Generation EPYC 64C 2GHz, AMD Instinct MI250X, Slingshot-11, HPE DOE/SC/Oak Ridge National Laboratory United States	8,699,904	1,206.00	1,714.81	22,786
2	Aurora - HPE Cray EX - Intel Exascale Compute Blade, Xeon CPU Max 9470 52C 2.4GHz, Intel Data Center GPU Max, Slingshot-11, Intel DOE/SC/Argonne National Laboratory United States	9,264,128	1,012.00	1,980.01	38,698
3	Eagle - Microsoft NDv5, Xeon Platinum 8480C 48C 2GHz, NVIDIA H100, NVIDIA Infiniband NDR, Microsoft Azure Microsoft Azure United States	2,073,600	561.20	846.84	
4	Supercomputer Fugaku - Supercomputer Fugaku, A64FX 48C 2.2GHz, Tofu interconnect D, Fujitsu RIKEN Center for Computational Science Japan	7,630,848	442.01	537.21	29,899
5	LUMI - HPE Cray EX235a, AMD Optimized 3rd Generation EPYC 64C 2GHz, AMD Instinct MI250X, Slingshot-11, HPE EuroHPC/CSC Finland	2,752,704	379.70	531.51	7,107

Taken from the June 2024 list of the Top500

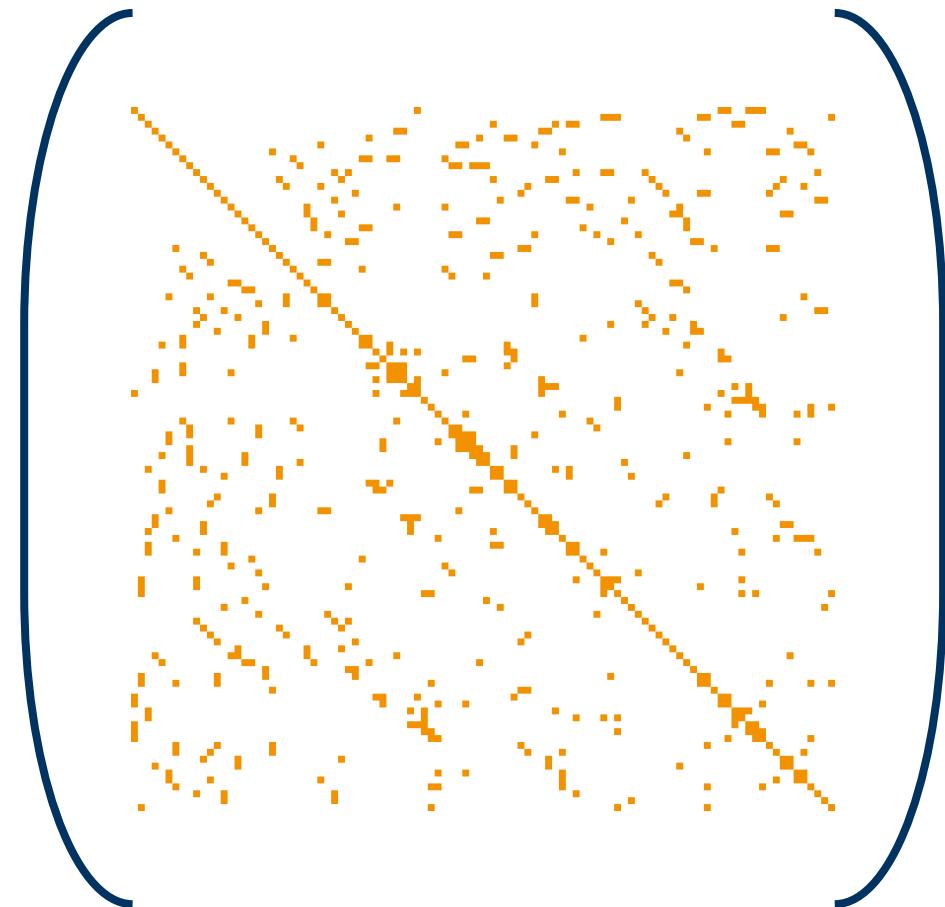

Dense linear algebra: optimizations

- ▶ loop blocking or tiling
 - ▶ do not work on single elements but smaller blocks (e.g. 2x2 or 32x32)
 - ▶ exploits locality and cache
 - ▶ also, lots of other HOTs (Higher Order Transformations)
- ▶ vectorization (SIMD, e.g. SSE/AVX)
 - ▶ might entail modifications, e.g. transposing matrix A or B in matrix mul
- ▶ hardware-specific instructions
 - ▶ e.g. fused multiply-add (FMA)

```
for (int ii = 0; ii < N; ii += ib) {  
    for (int jj = 0; jj < N; jj += jb) {  
        for (int k = 0; k < N; ++k) {  
            for (int i = ii; i < ii+ib; ++i) {  
                for (int j = jj; j < jj+jb; ++j) {  
                    // ... process single tile  
                }  
            }  
        }  
    }  
}
```

Sparse linear algebra

- ▶ data is stored in sparsely-populated matrices (or vectors)
 - ▶ (vast) majority of data is zero
 - ▶ data is stored in compressed format
 - ▶ data often accessed indirectly via indices
- ▶ e.g. conjugate gradient, Google's PageRank, data mining

Sparse linear algebra: characteristics

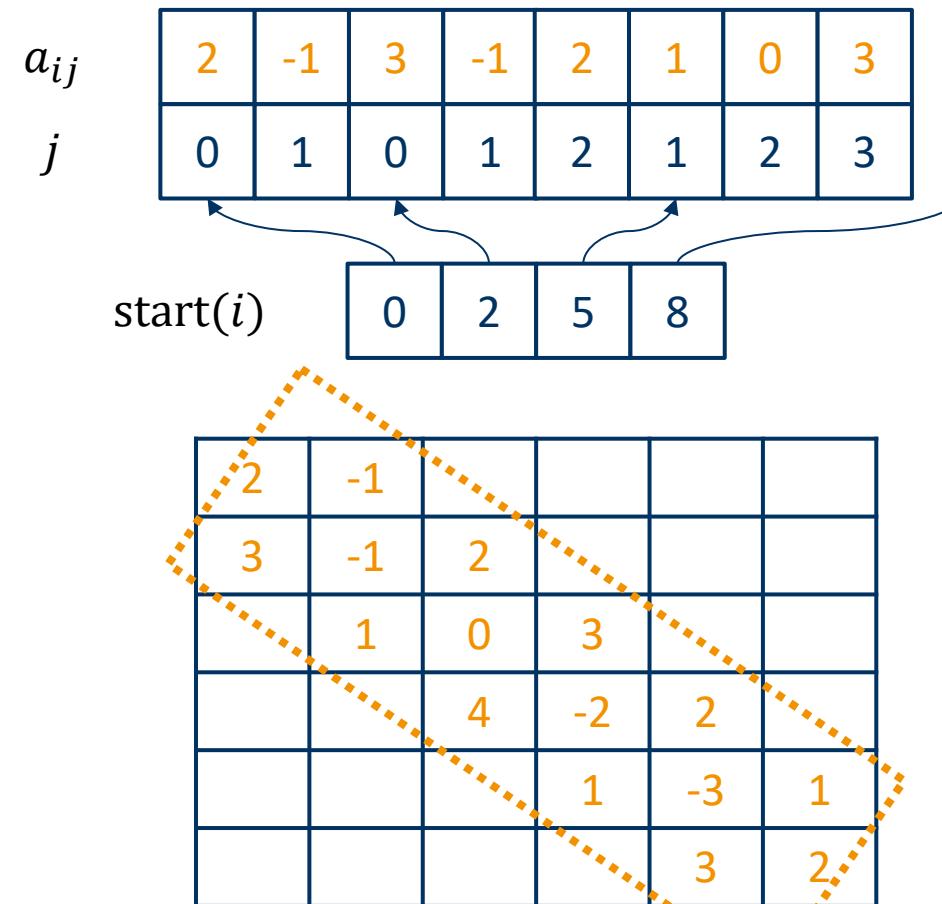

- ▶ computationally or memory limited
 - ▶ depends on sparsity of data, data structure representation and algorithm
- ▶ different data structures available
 - ▶ e.g. coordinate scheme (COO) or “triplet format” or similar: (i, j, a_{ij})
 - ▶ array of structs (AoS) vs. struct of arrays (SoA)
 - ▶ not necessarily sorted!

```
typedef struct sparseElement {  
    int i; int j; double value;  
} sparseElement;  
sparseElement sparseMatrix[SIZE];  
sparseMatrix[0].i = 0;  
  
// ##### vs. #####  
  
typedef struct sparseMatrixT {  
    int i[SIZE]; int j[SIZE];  
    double values[SIZE];  
} sparseMatrixT;  
sparseMatrixT sparseMatrix;  
sparseMatrix.i[0] = 0;
```

Sparse linear algebra: optimizations

- ▶ compressed row storage (CRS)
 - ▶ two arrays of size N
 - ▶ one holds a_{ij} , the other j
 - ▶ third array points to start of row i in j
 - ▶ smaller memory footprint than COO
 - ▶ $2N + (m + 1)$ vs. $3N$

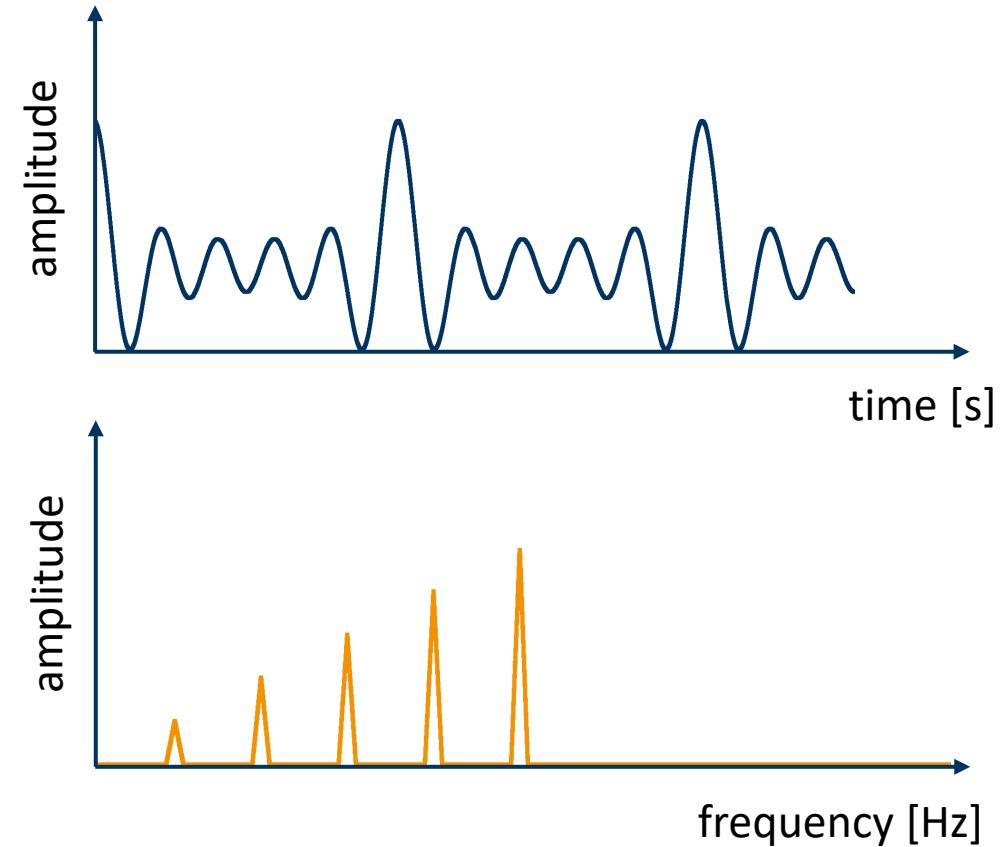

- ▶ variants
 - ▶ column-major variant (CCS)
 - ▶ store small blocks (2x2 or 4x4) instead of single elements, improves SIMDness
 - ▶ compressed diagonal storage (CDS)
 - ▶ use domain-specific knowledge!

Spectral methods

- ▶ data in frequency domain, not time or space
 - ▶ can include multiple stages of computations alternating between local and global communication

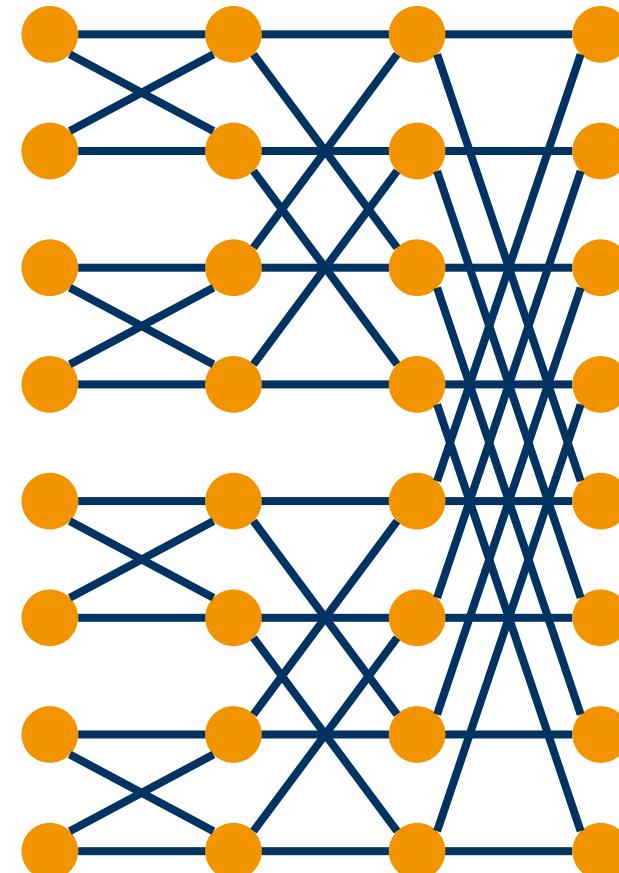

- ▶ e.g. fast Fourier transform (FFT), audio and video signal processing
 - ▶ e.g. “focus hunting” in contrast-based autofocus of photo/video cameras

Spectral methods: characteristics

- ▶ usually implemented using butterfly patterns
 - ▶ multiple stages of multiply-add
 - ▶ often latency limited due to global communication patterns (e.g. all-to-all)

- ▶ often resemble structured or unstructured grid methods after transformation to frequency domain

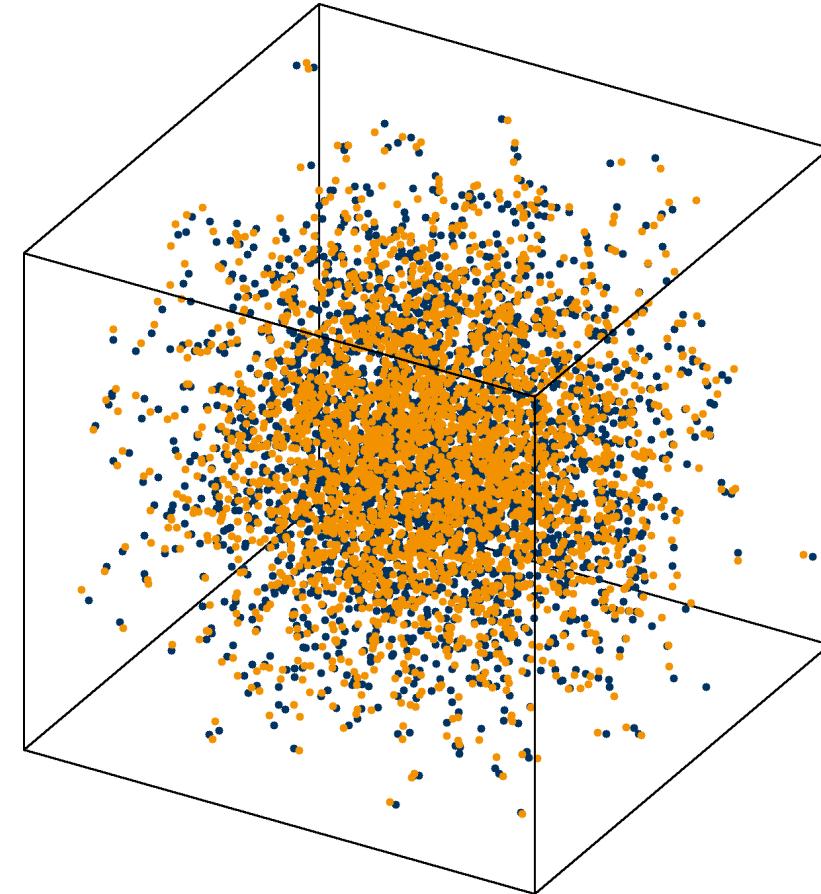

Spectral methods: optimizations

- ▶ requires optimization of the transformation to frequency domain
 - ▶ relies on transposing data efficiently
- ▶ afterwards, consider similar optimizations as for (un)structured grids
- ▶ severely restricted scalability on larger HPC systems
 - ▶ ongoing research
 - ▶ lots of it in math

N-body methods

- ▶ model interactions between discrete, moving points
 - ▶ often requires dynamic data structures
 - ▶ varying spatial locality
 - ▶ movement affects load balance and data access costs

- ▶ e.g. galaxy collision simulations, molecular dynamics, protein folding

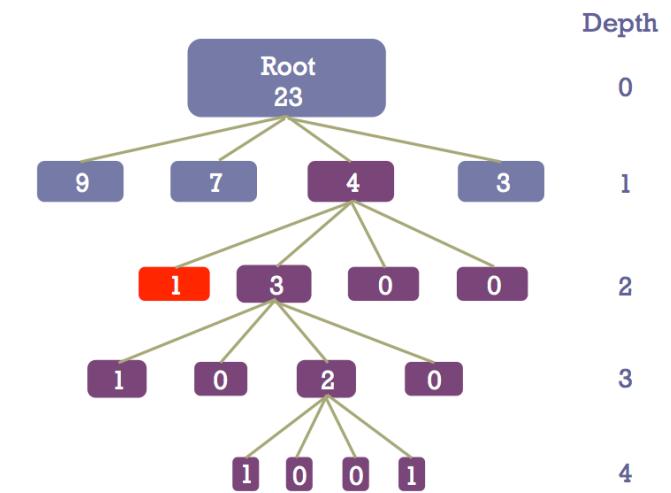

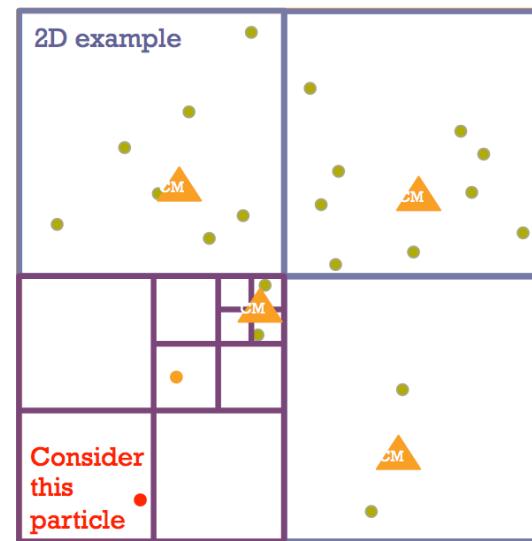

N-body methods: characteristics

- ▶ computational effort is an issue
 - ▶ $\mathcal{O}(N^2)$ for N particles
 - ▶ but also global communication
- ▶ lots of hierarchical optimization studies
 - ▶ domain decomposition!
 - ▶ e.g. Barnes-Hut or fast multipole optimization
- ▶ alternative approaches rely on domain-specific knowledge, e.g.
 - ▶ ignore long-distance particle interactions
 - ▶ store particles in Cartesian topology & only consider particles in neighboring grid cells

N-body methods: optimizations

► Barnes-Hut optimization:

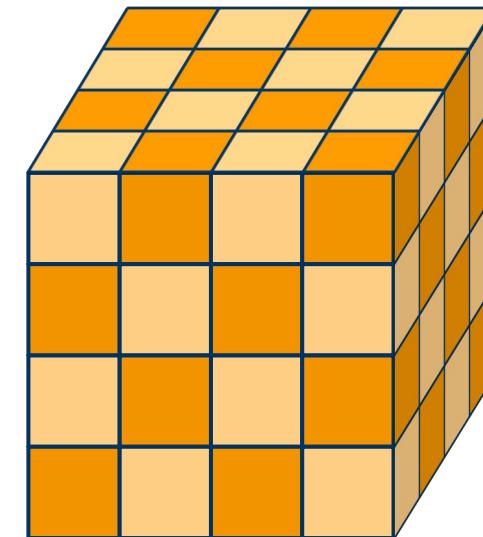

- ▶ decompose domain into quadtree (for 2D)
- ▶ aggregate particle effect (e.g. gravitation from mass) for each cell into a single (hypothetical) particle at the center of gravity per cell
- ▶ reduces complexity from $\mathcal{O}(N^2)$ to $\mathcal{O}(N \cdot \log N)$

Structured grids

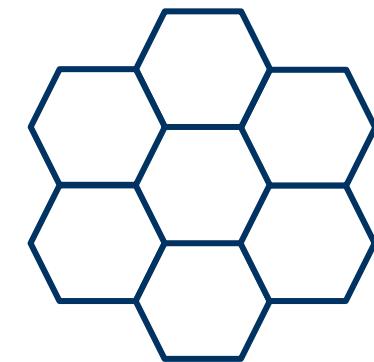

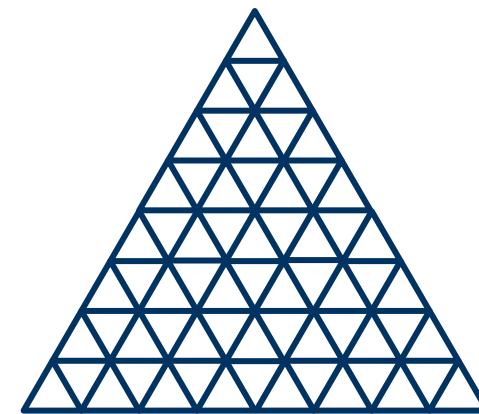

- ▶ model interactions between discrete, fixed points
 - ▶ grid structure described by pattern
 - ▶ topological information easily derived
 - ▶ usually high spatial locality
 - ▶ may be subdivided into finer grid (“adaptive”)

- ▶ e.g. heat transfer (stencil), computational fluid dynamics (CFD), octrees

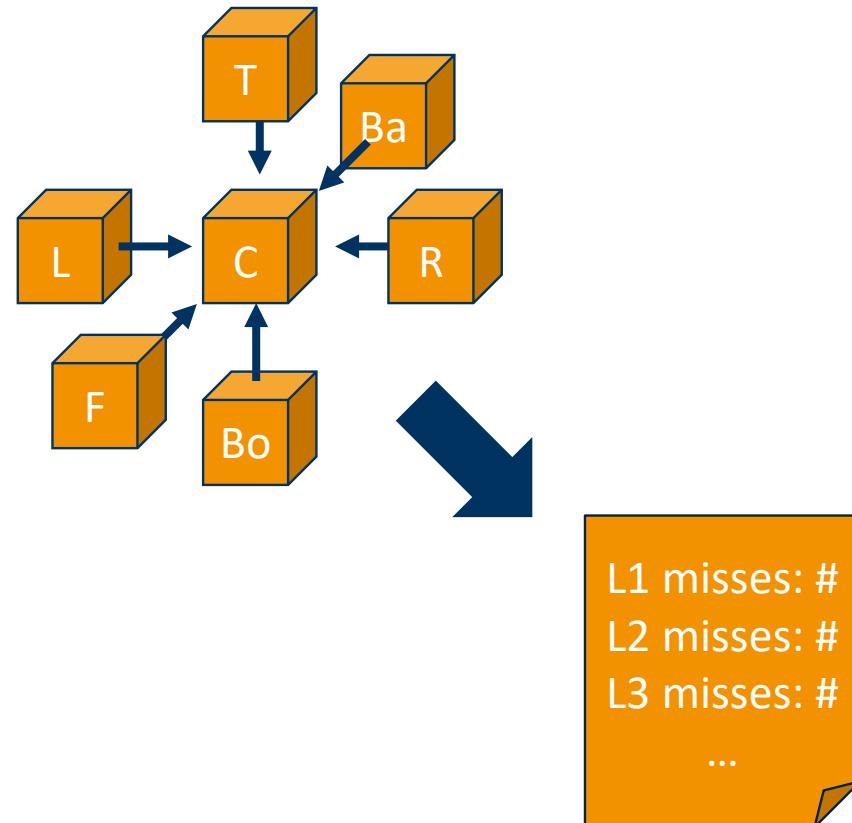

Structured grids: characteristics

- ▶ structured nature is a key aspect
 - ▶ similar characteristics compared to dense linear algebra (e.g. row-major vs. column-major)
 - ▶ memory access patterns & addresses often predictable, facilitates e.g. prefetching
 - ▶ adaptive grids and multi-grids possible
- ▶ typically memory bound
 - ▶ e.g. 7-point stencil in 3D: load 7 data points for computing a new one
 - ▶ local communication only (ghost cell exchange with direct neighbor)
- ▶ structured grid does not imply rectangular!

Structured grids: optimizations

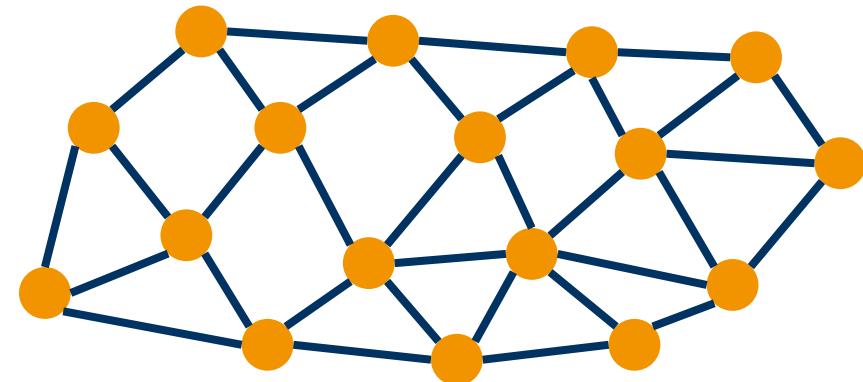

- ▶ decomposition, decomposition, decomposition
 - ▶ highly dependent on type of grid and specific use case
- ▶ structured nature of the problem makes analytic prediction possible
 - ▶ performance models and simulators for simple stencil kernels (e.g. Kerncraft)

Unstructured grids

- ▶ model interactions between discrete, fixed points
 - ▶ grid pattern described explicitly by individual connections
 - ▶ irregular geometry and topology
 - ▶ usually involves multiple levels of indirection when accessing data

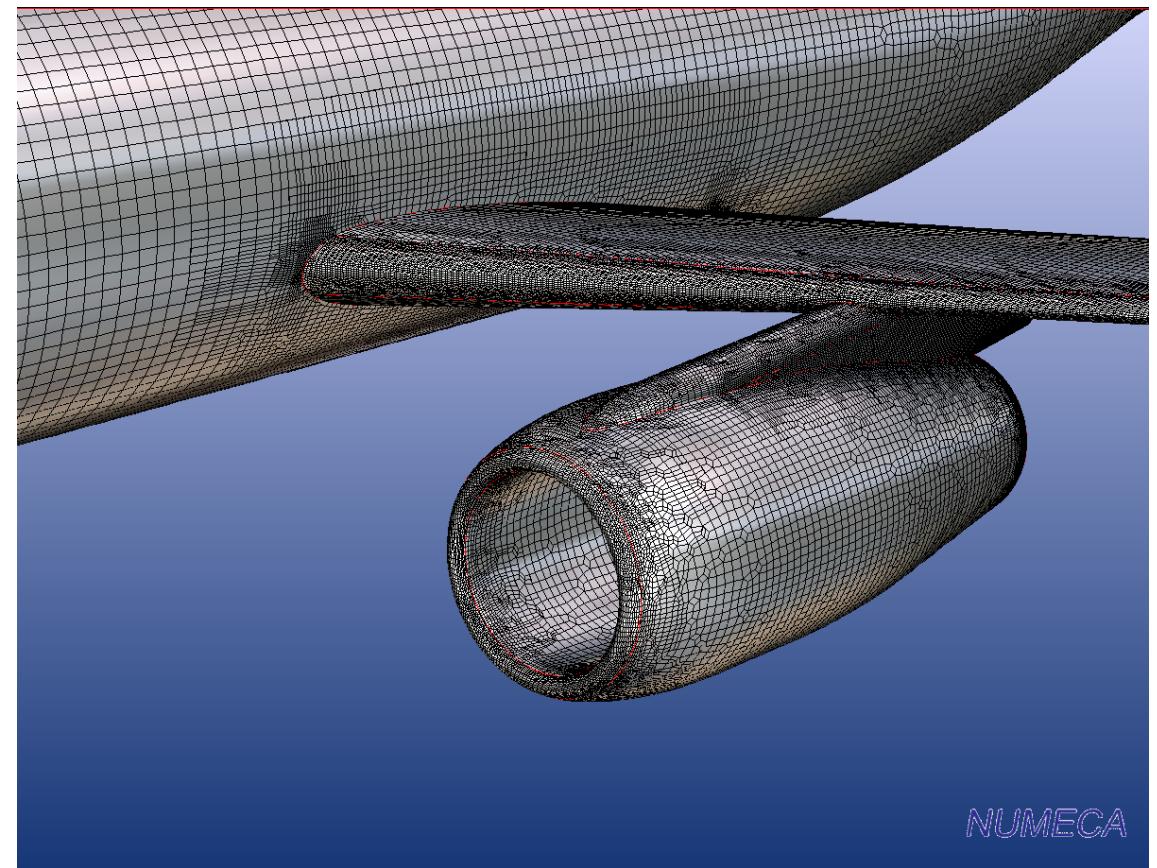

- ▶ e.g. computational fluid dynamics (CFD)

Unstructured grids: characteristics

- ▶ usually heavily latency bound due to indirect access
 - ▶ ... = `cells[neighbors[i]]`
 - ▶ ... = `cell.getNeighbor(i)`
 - ▶ also known as “pointer chasing”

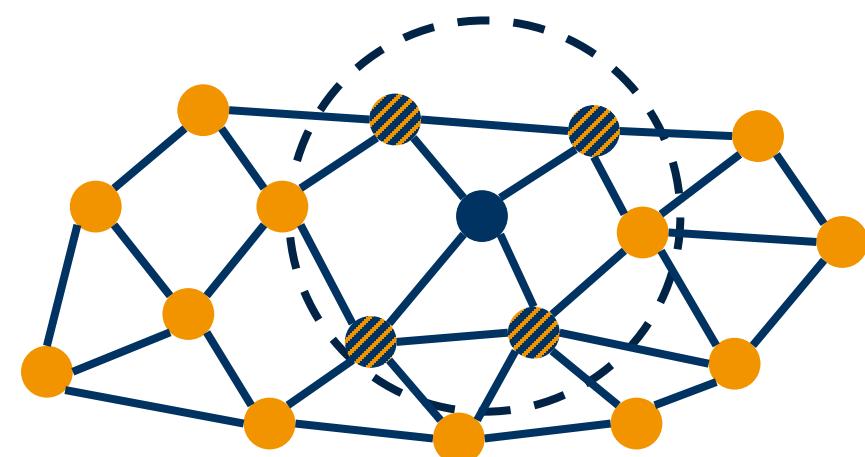

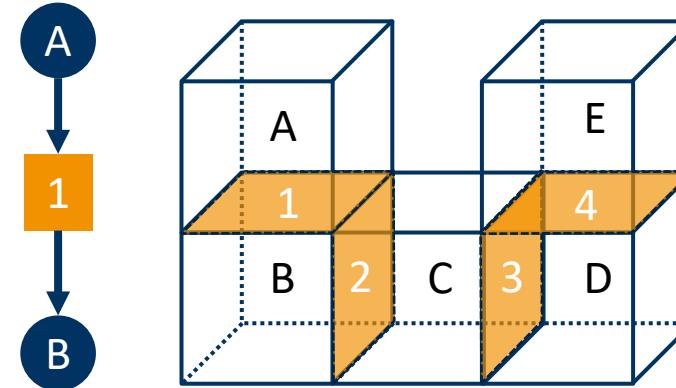

- ▶ similar problems compared to structured grids, e.g.
 - ▶ domain decomposition / adaptivity
 - ▶ topological information
 - ▶ ghost cell exchange
 - ▶ but hardly analytically predictable

Unstructured grids: optimizations

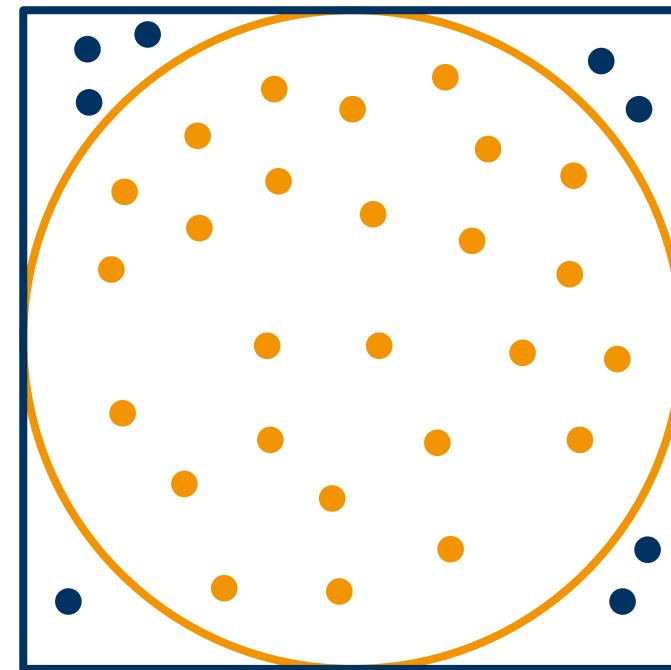

- ▶ problem space discretization and topology
 - ▶ which types of grid elements?
 - ▶ which types of connections?
 - ▶ cells, faces, vertices, edges, ...
 - ▶ should be efficient to load/store, navigate, and compute

- ▶ decomposition, decomposition, decomposition
 - ▶ efficient ghost cell exchange required
 - ▶ efficient grid navigation e.g. to access neighbors

Monte Carlo methods

- ▶ also known as map-reduce
 - ▶ process data independently and merge the results
- ▶ models statistical evaluation of repeated random trials
 - ▶ communication usually insignificant
 - ▶ embarrassingly parallel, multiple copies of sequential method
- ▶ e.g. numerical integration, quantum many-body problems, ray tracing

Monte Carlo methods: characteristics

- ▶ parallelization almost a no-factor
 - ▶ similar to multiple sequential programs sharing some resources
(e.g. L3 cache, random number generator, thermal envelope of CPU)
 - ▶ relatively inexpensive reduction
- ▶ depends heavily on sequential speed and shared bottlenecks

Monte Carlo methods: optimizations

- ▶ not much to do beyond sequential optimization
 - ▶ ILP
 - ▶ prefetching
 - ▶ vectorization
 - ▶ reduce resource contention
(read: fast random number generation)
- ▶ consider different hardware
 - ▶ GPUs
 - ▶ FPGAs
 - ▶ ...
- ▶ try to decrease cost of evaluating a sample
 - ▶ increase number of samples if required

Additional Dwarfs

Additional dwarfs

- ▶ 8. Combinational Logic
 - ▶ 9. Graph Traversal
 - ▶ 10. Dynamic Programming
 - ▶ 11. Backtrack & Branch+Bound
 - ▶ 12. Graphical Models
 - ▶ 13. Finite State Machine
-
- ▶ slightly different focus compared to first 7 dwarfs
 - ▶ more (but not exclusively) on integer-heavy applications, machine learning, theoretical problems
 - ▶ less on physical processes

Combinational logic

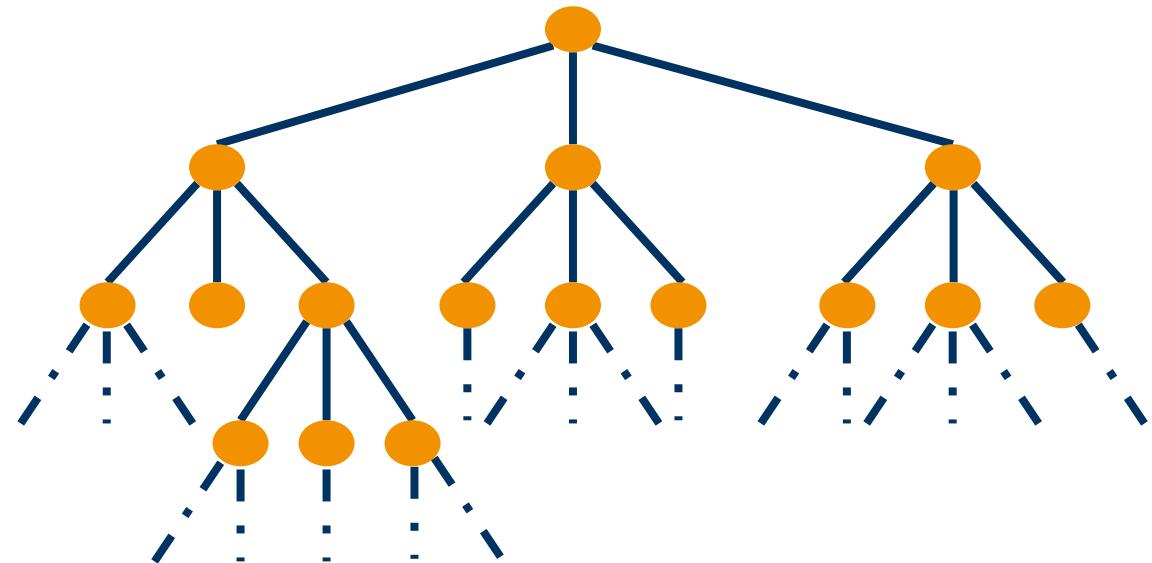

- ▶ generally involves performing simple operations on large amounts of integer data
 - ▶ e.g. computing cyclic redundancy codes (CRC)
- ▶ often parallelizable on multiple levels
 - ▶ bit-level parallelism (e.g. x86 popcnt)
 - ▶ block-level parallelism

```
uint8_t compute(uint8_t const msg[], int n) {  
    uint8_t rem = 0;  
    for (int byte = 0; byte < n; ++byte) {  
        rem ^= (msg[byte] << (WIDTH - 8));  
        for (uint8_t bit = 8; bit > 0; --bit) {  
            if (rem & TOPBIT) {  
                rem = (rem << 1) ^ POLYNOMIAL;  
            } else {  
                rem = (rem << 1);  
            }  
        }  
    }  
    return (rem);  
}
```

Graph traversal

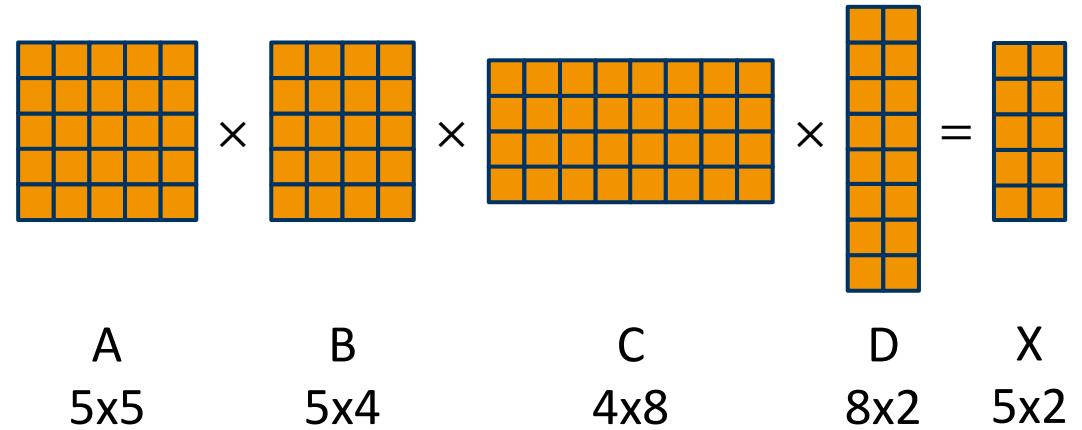

- ▶ traverse a number of objects in a graph and examine characteristics
 - ▶ e.g. searching, sorting, collision detection, decision trees, ...
 - ▶ usually heavy on data reads and lookups, very little computation and output

- ▶ parallelizable over different paths in the graph
 - ▶ but indirect accesses are heavily latency-bound (c.f. unstructured grids)

Dynamic programming

- ▶ method of computing solutions by solving simpler, overlapping sub-problems
 - ▶ applicable to problems where optimal result is composed of optimal results of sub-problems
 - ▶ e.g. matrix-chain-multiplication
- ▶ usually based on memoization
 - ▶ solve each sub-problem exactly once
 - ▶ store and re-use the result

$$A \times (B \times (C \times D)) = X \quad 154 \text{ ops}$$

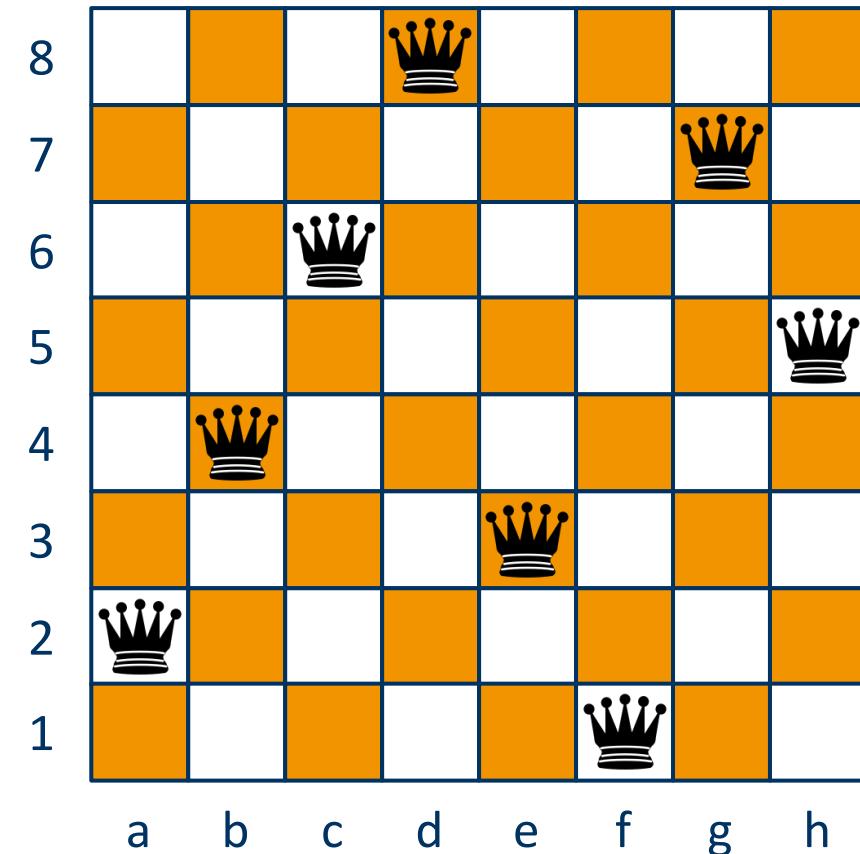

$$(A \times B) \times (C \times D) = X \quad 204 \text{ ops}$$

$$((A \times B) \times C) \times D = X \quad 340 \text{ ops}$$

Backtrack & Branch+Bound

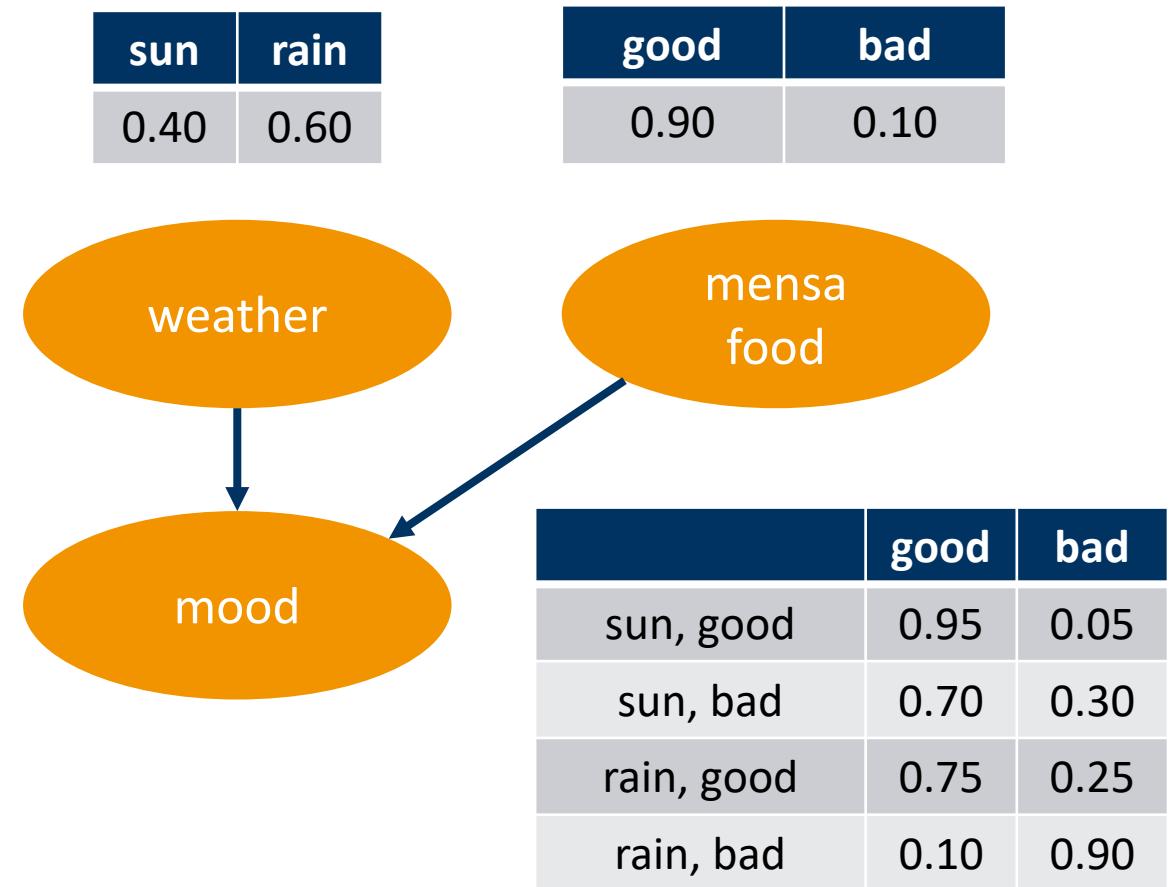

- ▶ search and optimization problems for very large problem spaces
 - ▶ incrementally build solution but discard if determined unsuitable
 - ▶ e.g. n-queens problem

- ▶ use divide & conquer strategy:
 - ▶ break down complex problem into smaller sub-problems until they become solvable
 - ▶ solve sub-problems in parallel

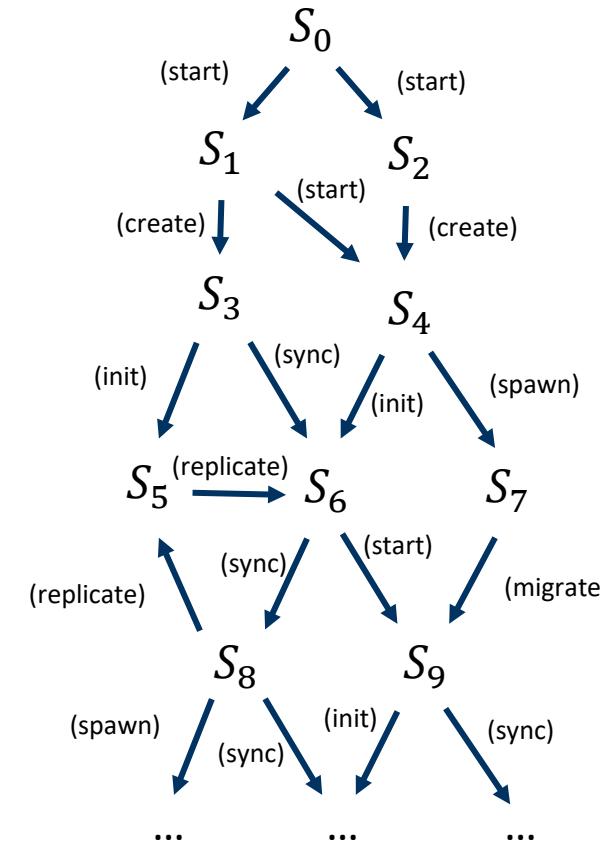

Probabilistic graphical models

- ▶ represent graphs consisting of random variables as nodes and dependencies as edges
 - ▶ e.g. Bayesian networks, Hidden Markov models
- ▶ ongoing research in math and computer science regarding parallelization and optimization

Finite state machines

- ▶ represent interconnected set of states to be moved among
 - ▶ e.g. parsers
- ▶ can sometimes be decomposed into multiple state machines that act in parallel
 - ▶ ongoing research

Literature material

- ▶ White Paper by Berkeley University: „The Landscape of Parallel Computing Research: A View from Berkeley” from 2006:
<https://www2.eecs.berkeley.edu/Pubs/TechRpts/2006/EECS-2006-183.pdf>
- ▶ Holds more detailed descriptions and related aspects

Note the focus on scientific problems

- ▶ MPI can be (and is!) used to implement also
 - ▶ distributed-memory runtime systems
 - ▶ emulate shared memory runtime systems on distributed memory (e.g. PGAS)
 - ▶ provide the connecting parallelism layer for shared-memory or sequential systems
 - ▶ e.g. use multiple accelerators in separate compute nodes (Celerity project @ UIBK)
 - ▶ extend shared memory parallelism to distributed memory (MPI+X)
 - ▶ ...
- ▶ still, the majority of codes is of scientific computing nature

Summary

- ▶ **13 Dwarfs of HPC**
 - ▶ abstract application categories
 - ▶ facilitate cross-platform reasoning and cross-application component reuse
 - ▶ 7 older ones, most well-studied physics problems
 - ▶ 6 newer ones, partially of theoretical nature, subject to ongoing research
 - ▶ give a broad perspective on HPC potential and limitations
